Using the halo model fits, we estimate the minimum dark matter mass scale for dusty star-forming galaxies at the peak of the star formation history of the universe to be $\log_{10} M_{\text{min}}/M_{\odot} = 11.5_{-0.2}^{+0.7}$ at $350 \mu\text{m}$ with a bias factor for the galaxies of $2.4_{-0.2}^{+1.0}$. The minimum halo masses $\log_{10} M_{\text{min}}/M_{\odot}$ at 250 and $500 \mu\text{m}$ are $11.1_{-0.6}^{+1.0}$ and $11.8_{-0.3}^{+0.4}$, respectively. The corresponding bias factors for the galaxies are $2.0_{-0.1}^{+0.9}$ and $2.8_{-0.5}^{+0.4}$ at 250 and $500 \mu\text{m}$, respectively. The differences in the minimum halo masses and the bias factors between the three wavelengths are likely due a combination of effects including overall calibration uncertainties, the fact that at longer wave-
