# Assignment

---

- Format

- 45 minutes broken as follows: a 15 minute (uninterrupted) presentation of the major science goals, 5 minutes of discussion, 10 minutes (uninterrupted) of suggested projects and then 15 minutes of open discussion

# Major Science Goals

# Goals

## Revolutionary Goal

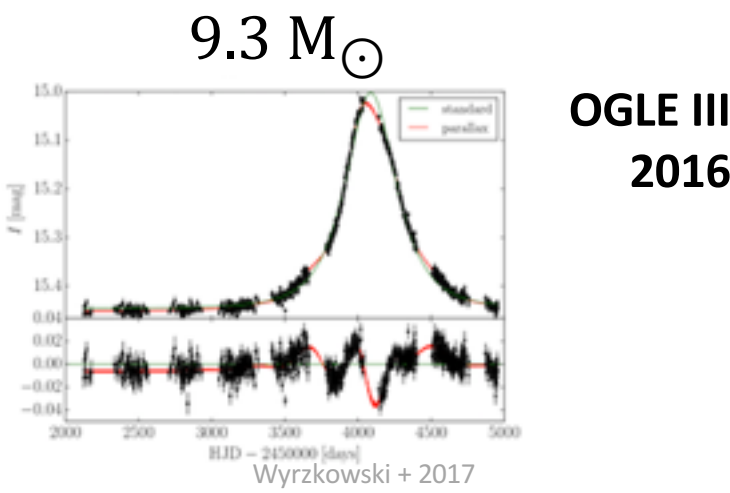

Confirm or reject Intermediate Mass MACHOs as the majority of dark matter.

## Conservative Goal

Make the first direct measurement of the mass spectrum of black holes in the Milky Way.

# Black Hole Dark Matter

# Intermediate Mass Black Holes Have been observed

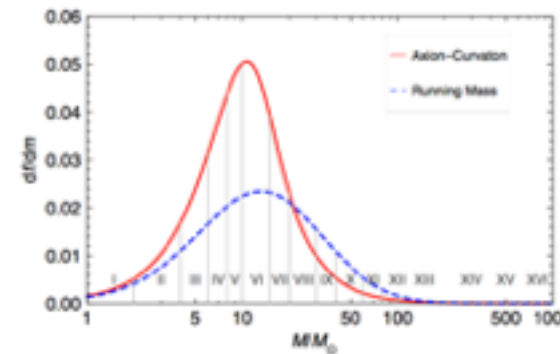

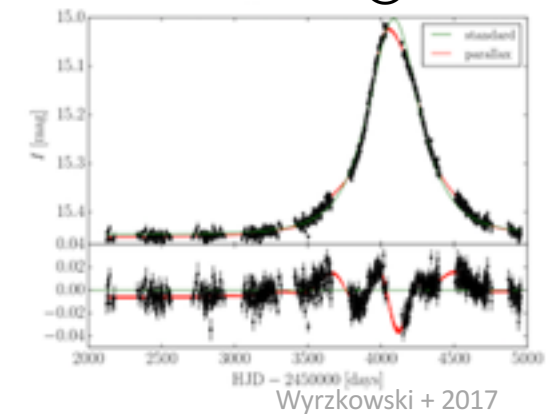

# Intermediate Mass Black Holes Have been observed

- Also extensive primordial black hole literature: from Chapline (1975) to Carr et al. (2016).
- Current LIGO event rate is consistent with intermediate mass black holes making up all dark matter (Bird et al. 2016)
- If primordial BHs make up dark matter, then measuring their mass spectrum will be especially exciting because it will tell us something about the fundamental physics of the Big Bang.

## EXTENDING THE MACHO SEARCH TO $\sim 10^6 M_\odot$

ANDREW GOULD

Institute for Advanced Study, Princeton, NJ 08540

Received 1991 November 4; accepted 1991 December 27

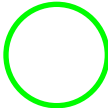

### ABSTRACT

The search for a microlensing (changing light-curve) signature of massive compact halo objects (Machos) by the Macho Collaboration is currently believed to be sensitive in the range  $10^{-7}$ – $10^2 M_\odot$ . Microlensing events from higher mass objects last longer than the 4 yr duration of the planned experiments and therefore, according to current beliefs, cannot be distinguished from long-term variables. In fact the signature of Machos in the range  $10^2$ – $10^3 M_\odot$  can be distinguished from background events by the annual modulation in light magnification induced by the Earth's motion. For Machos in the range  $10^3$ – $10^6 M_\odot$ , *Hubble Space Telescope* (HST), or even ground-based measurements can resolve the split lensed images, thus confirming the lens interpretation of an event. If the HST's optics were repaired, it could resolve images for Machos  $\gtrsim 300 M_\odot$ . The lower mass limit can be reduced to  $4 \times 10^{-9} M_\odot$  by conducting 1 month of rapid repeat observations of a single field. The standard view is that a Macho light curve yields only one physically relevant parameter, the time scale of the event. The time scale is a combination of the four parameters one would like to know: the mass, the distance, and the two components of transverse velocity of the Macho. I show that for masses 4–100  $M_\odot$ , annual parallax oscillations in the light curve can be used to determine the transverse velocity. In the range  $10^{-3}$ – $10^6 M_\odot$  such measurements can be made using a small special-purpose satellite telescope. For masses  $10^3$ – $10^6 M_\odot$ , one may determine all four Macho parameters by combining a number of techniques.

*Subject headings:* astrometry — Galaxy: halo — gravitational lensing — techniques: photometric

# Microlensing also affects the astrometry of the source star

# Intermediate Mass MACHO signal provides powerful background discrimination.

- Achromatic
  - Same signal across all wavelengths
- Parallax
  - Signal highly correlated with known motion around the sun
- Astrometry
  - Independent measurement; signal highly correlated with photometric signal

# But microlensing is not the only way forward

- Astrometry (Gaia)
- Massively multiplexed spectroscopy (LAMOST, SDSS Phase V, DESI)
- Black hole accreting from stellar wind (Cygnus X-1)
- Black hole accreting from disk (MAXI; A0620-00)
- Accretion of ISM (SKA,SRG)
- Ellipsoidal Modulation (ZTF, TESS) followed by radial velocity (SDSS, DESI)
- Narrow & Wide-band H-alpha imaging (future ZTF project?)
- Strong lensing by a background star (OGLE, ZTF)
- Lensing of secondary star (orbital plane perpendicular to the plane of the sky)
- Variations in eclipse time (OGLE)
- Radio-X-ray "fundamental plane" relation (VLA, SRG)
- Sub-millimeter transients (future facility)
- **Your method here**

# Black hole lens or boring old star lens?

# There is often ambiguity about whether a microlensing lens is truly dark

- Consider two MACHO microlensing candidate black hole events
- Possible black holes but also consistent with simple star-star lensing

FATIMA N. ABDURRAHMAN

MICROLENSING 23. JAN 29 2019

## MACHO-98-BLG-6 AND MACHO-96-BLG-5

- ▶ Detected by MACHO Survey in 1998 and 1996
- ▶ Bennet et al 2002:
  - ▶ M98:  $M/M_{\odot} = 6^{+7.3}_{-3}$
  - ▶ M96:  $M/M_{\odot} = 6^{+10.3}_{-3}$
- ▶ Poindexter et al 2005:
  - ▶ M96 is a marginal BH candidate (37%)
  - ▶ M98 is a weak BH candidate (2.2%)
- ▶ Difficult to break degeneracies in light curves, so galactic models often needed

Figure: Bennet et. al. 2002

# One option is to wait a decade or two and see if the lens moves into plane sight

- Requires high resolution imaging from space and ground over a very long temporal baseline, often much longer than the duration of the event
- Radial velocities and “chromatic microlensing” offer a way to break this degeneracy on much shorter timescales

# Microlensing and Radial Velocity Complementarity
